2.1 Dataset

The dataset used is a subset of the data collected in the National Health and Nutrition Examination Survey (NHANES). The survey is a part of annual program that investigates the health and nutrition of a representative sample of people in the United States. The data we used contains information about 525 individuals

that has been collected for the NHANES 2007-2008. This is a subset of the 12,946 individuals in that years' survey sample, out of which 78.4% was interviewed and 75.4% was examined in mobile examination centers.

The used dataset contains a wide range of variables related to the health of the individuals. We further subset the data by only including variables relevant to the study (demographics, alcohol use and answers to depression screener questions). The selected variables are further described in Variable Description section.

2.2 Data variables

Table 1: Variable descriptions

Role	Variable	Name	Type	Characteristics	Target
Outcome	Drink regularly	drink_regularly	Categorical	Binary, yes and no	m/f, age 20-150
Predictor	Sex	sex	Categorical	Binary, male and female	m/f, age 0-150
Predictor	Age	age	Numeric	Discrete	m/f, age 0-150
Predictor	Ethnicity	ethnicity	Categorical	Nominal, 5 categories	m/f, age 0-150
Predictor	Education	marital	Categorical	Nominal, 5 categories	m/f, age 20-150
Predictor	Marital status	marital	Categorical	Nominal, 5 categories	m/f, age 20-150
Predictor	Household income	household_income	Categorical	Nominal, 12 categories	m/f, age 0-150
Predictor	No interest in activity	dep1	Categorical	Ordinal, 1-3 scale	m/f, age 18-150
Predictor	Feeling depressed	dep2	Categorical	Ordinal, 1-3 scale	m/f, age 18-150
Predictor	Sleeping issues	dep3	Categorical	Ordinal, 1-3 scale	$\rm m/f,~age~18\text{-}150$
Predictor	Feeling tired	dep4	Categorical	Ordinal, 1-3 scale	m/f, age 18-150
Predictor	Eating issues	dep5	Categorical	Ordinal, 1-3 scale	m/f, age 18-150
Predictor	Feeling bad about yourself	dep6	Categorical	Ordinal, 1-3 scale	m/f, age 18-150
Predictor	Concentrating issues	dep7	Categorical	Ordinal, 1-3 scale	m/f, age 18-150
Predictor	Moving and speaking issues	dep8	Categorical	Ordinal, 1-3 scale	m/f, age 18-150
Predictor	Suicidial thoughts	dep9	Categorical	Ordinal, 1-3 scale	$\rm m/f,age~18\text{-}150$

Table 1 lists the variables used in our subset selection, which will be utilised for the model in question. The predictor variables [dep1...dep9] are sourced from the same Depression Screener, where respondents of age 18 to 150 were ought to assign a number (1 to 3) regarding their mental and physical state within the last 2 weeks. Multiple signs of depression were measured this way, which can later be combined to indicate an overall level of depression.

The demographic variables - that being sex, age, ethnicity, education and household_income - were taken from the same screening component as well. The following should be noted, regarding these demographic variables:

- The variable age is topcoded at the value 80 for the respondents who were older than 80 years.
- The variable education was targeted at respondents of age 20 to 150, thus excluding younger participants. This is due to the fact that this question includes responses such as AA degree and College Graduate.
- Similarly, the variable marital was also targeted at respondents of age 20 to 150.
- The variable household income is ordinal, rather than continuous.

As for the remaining demographic variables, namely sex, age, ethnicity and household_income, these are retrieved from target age 0 to 150.

Finally, the drink_regularly variable was obtained from an Alcohol Use questionnaire targeted at ages 20 and up.

2.3 Data processing methodology

• what we investigated and why

2.4 Model methodology

3 EDA Results (Nisse)

3.1 Descriptive statistics

Table 4 from the Appendix 5 shows summary statistics for each of the variables within the dataset; including mean values, standard deviations, IQR statistics and data range values. For categorical variables, a list of possible categories and their respective proportions is provided to replace the continuous summary statistics. Lastly, the column N shows the amount of cases with present data - that being non-NA values.

In general, it is worthy to note that all variables are interpreted as a factor, excluding age and the multiple depression levels of dep. Table 1 suggests that dep should in fact be categorical ordinal and should therefore be cast as a factor. That said - and as mentioned in Section 2 - keeping the levels of dep as a numerical continuous datatype is beneficial for our missing data problem.

Our dichotomous outcome variable drink_regularly has 307 cases of "yes" and 107 cases of "no", having a outcome balance of 69% and 31% respectively. This outcome ratio could be considered imbalanced, which could affect the accuracy of our logistic regression model. Additionally, the total amount of value entries (N) of 446 suggests that 79 cases contain values outside of the set of possible binary values - most likely being missing values. Table 2 further confirms this.

Table 2: Drink regularly value distributions

drink_regularly	n
yes	307
no	139
NA	79

Predictor sex is a dichotomous variable with a balanced frequency distribution across the values "male" and "female", that being 48% and 52% respectively. 525 entries contain one of these values, suggesting that the variable does not contain missing data.

The predictor age is the only continuous variable present within the sub-selected dataset. Although the survey was targeted at respondents of age 0-150 for most variables - the documentation even mentioning the topcoded entries for age 80+ - the dataset seems to only contain cases of people between the age of 20 and 69. Moreover, Figure 1 suggests a uniform distribution of the age variable. Like sex, age has 525 cases with non-NA values, hence the variable does not contain missing data values.

Predictor ethnicity has 5 categories, with non-hispanic_white being the most prevalant category with 220 cases (42% of total), all the while other is the most infrequent category with 25 cases (5%). A total of 525 cases contain ethnicity data, once again suggesting no presence of missing data values within this variable.

Predictor education is similar to ethnicity, having 5 categories. That said, the frequencies of said categories seem to be less out of proportion, with some_college being the most frequent category with 155 (30%) cases. Whilst the data was retrieved from respondents of ages 20 and higher, we do not observe any missing data values within the variable. This can be further justified by the fact that the minimum age within our dataset is 20, therefore foregoing possible issues with younger participants being unable to provide data for this specific variable.

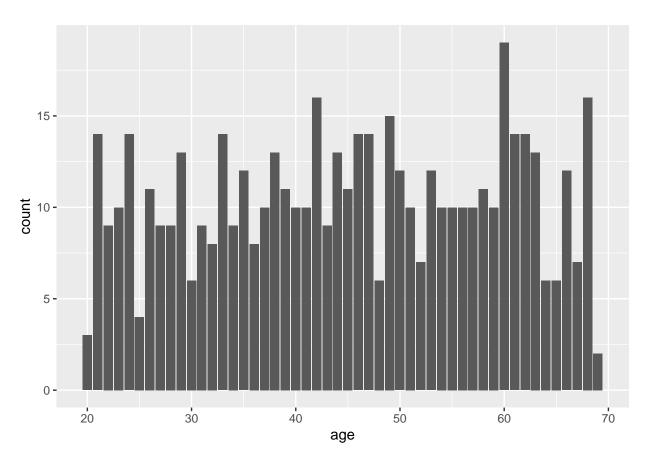

Figure 1: Distribution of age

The predictor variable marital contains 6 categories. Prior to combining the marital categories, the category value married exceeded the the average frequency of other categories (that being 49.2) by a large margin - as can be seen in Figure 2. Specifically, 279 cases (53%) were married, with the other 5 categories made up the remaining 47% of the cases. never_married was the most frequent among those other 5 categories with 102 (19%) cases, whilst separated was the most infrequent category with only 14 (3%) cases.

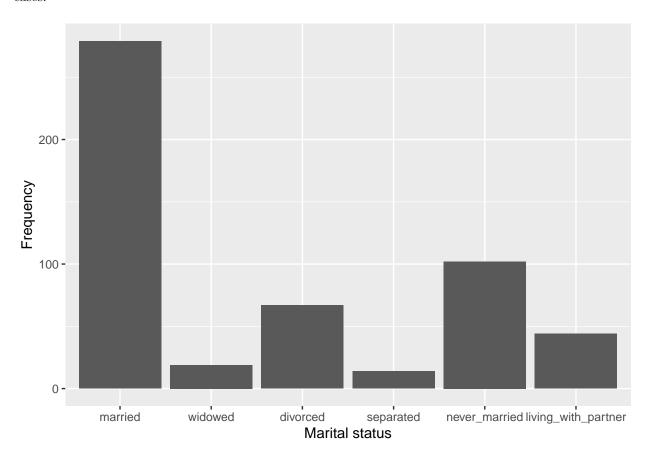

Figure 2: Distribution of marital status categories before pre-processing

3.2 Correlations

Table 3: Contigency table of marital vs. drink regularly

	yes	no
married	175	81
widowed	8	11
divorced	48	14
separated	8	4
never_married	45	23
living_with_partner	23	6

```

3.3 Outliers

For our only continuous predictor age, a boxplot shows potential outliers if datapoints fall outside of the interquartile range (whiskers of the plot). Figure ?? shows the distribution of age in said boxplot, revealing no possible outliers. This is to be expected, since age was uniformly distributed as mentioned in Section 3.1.

As for our categorical predictors,

Figure 3 shows the frequencies per marital category after the pre-processing step of combining the other values into one.

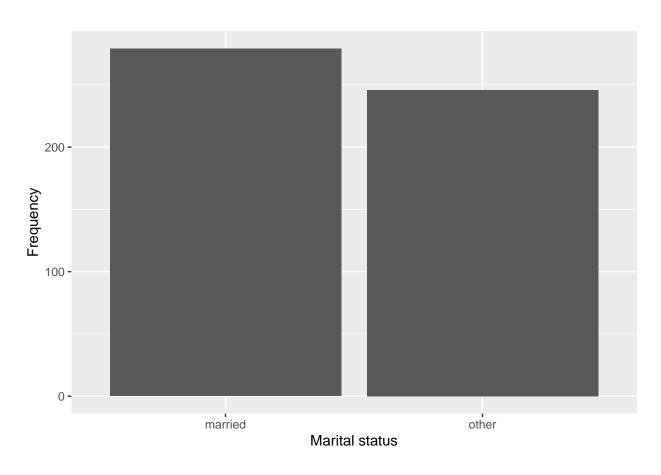

Figure 3: Distribution of marital status categories after pre-processing

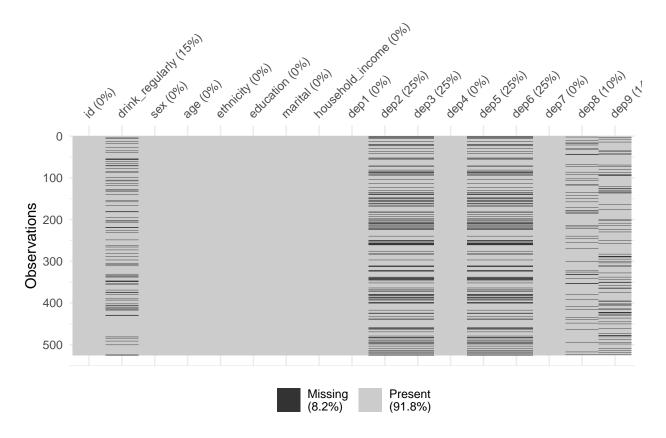

3.4 Relations

4 Missing data problem (Aga)

4.1 Missing data and response Patterns

Firstly, we investigate the overall distribution of missing data in our dataset:

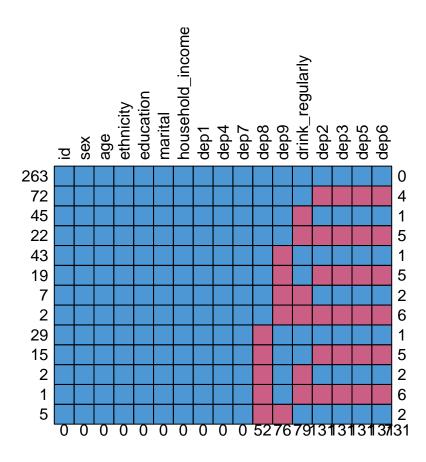

```
# Creates a graph displaying the % of data missing in each variable
vis_miss(data)
```

As can be seen on the graph above, 8.2% of the data is missing. The missing values occur in the outcome variable 'drink_regularly' and in the responses to questions 'dep2', 'dep3', 'dep5' and 'dep6'that create the depression score variable. 15% of responses are missing for the predictor variable and 25% of the responses are missing for the individual depression questions.

We further investigate the missing data patterns by looking at the response patters:

```
#Creates a graph with all of the response patterns in the dataset and their frequency
md.pattern(data, rotate = TRUE)
```

                                               131
                                                     131 731
```

This figure reveals that there are four distinct response patterns in the dataset. The most frequent one is no missing entries, with 340 cases. Alternatively, either all four depression entries are missing (106 cases), the predictor variable is missing (54 cases) or both (25 cases). It is very probable that the reason for item non-response for the depression items is the same, since there are no cases of only some of them missing. Since the depression items are missing in this pattern, 25% of the overall depression score will be missing.

```
# Creating vectors that indicate if a value is missing in a given variable. Since the pattern in depres
mdrink <- is.na(data$drink_regularly)</pre>
mdep <- is.na(data$dep2)</pre>
# Testing dependency between missing value in var1 and values of var2. Null hypothesis: no dependency.
out1 <- t.test(age ~ mdrink, data = data)</pre>
out1$statistic
        Testing dependency of missing values
